(54) Title: **VEGETABLE ROOM FOR REFRIGERATOR**

(57) Abstract: A vegetable room for a refrigerator includes: a vegetable box (20) disposed inside a refrigerator in which a cooling air supply unit is provided to circulate cooling air therein and a plurality of shelves (10) are provided, and having a receptacle space (5) for receiving food items therein opened upwardly; a box cover (30) for covering an opening side of the vegetable box (20) to close the receptacle space (5) of the vegetable box (20) and having a plurality of cooling air ventilating holes (31, 41) formed at one side thereof to introduce cooling air into the vegetable box (20); a cover support unit (22) interposed between the box cover (30) and the shelf (10) to support the box cover at the shelf; a plurality of opening and closing members (33, 43) for opening and closing the cooling air ventilating holes (31, 41) of the box cover (30); and an operating unit (24) for operating the opening and closing members (33, 43) simultaneously.

VEGETABLE ROOM FOR REFRIGERATOR

TECHNICAL FIELD

The present invention relates to a vegetable room for a refrigerator and,
5 more particularly, to a vegetable room for a refrigerator that is capable of
keeping storage stuff fresh for a long period regardless of environmental
conditions outside a refrigerator

BACKGROUND ART

10 In general, a refrigerator includes a freezing chamber for preserving
freezing food items, a refrigerating chamber for keeping refrigerating food items,
and a refrigerating cycle for supplying cooling air to the freezing chamber and
the refrigerating chamber. A vegetable room is provided at a lower side of the
refrigerating chamber to generally keep fruits, vegetables or functional storage
15 items.

Figure 1 is a vertical-sectional view showing one example of a
refrigerator in accordance with a conventional art.

The conventional refrigerator includes: a main body 100 having a
receptacle space therein, a freezing chamber 103 disposed at an upper portion
20 of the main body 100 and keeping freezing items, a refrigerating chamber 109
disposed at a lower portion of the main body 100 by being partitioned from the
freezing chamber 103 by a wall 105 and having a plurality of shelves 107 for
receiving refrigerating food items, a freezing chamber door 111 and a

refrigerating chamber door 112 respectively mounted to be opened and closed forwardly of the freezing chamber 103 and the refrigerating chamber 109; a cooling air supply unit installed at a rear side of the refrigerating chamber 103 and supplying air cooled while passing a refrigerating cycle to the freezing chamber 103 and the refrigerating chamber 109; and a vegetable room provided at a lower side of the refrigerating chamber 109 and keeping fruits, vegetables or functional storage items.

The refrigerating cycle includes a compressor 104 for changing a low temperature and low pressure gaseous refrigerant to a high temperature and high pressure gaseous refrigerant; a condenser (not shown) for condensing the gaseous refrigerant which has been compressed in the compressor 104 to a liquid state and externally discharging heat; an expander (not shown) formed as a capillary tube for changing the refrigerant in the liquid state as changed in the condenser to a low temperature and low pressure saturated liquid state; and an evaporator 106 for evaporating the refrigerant in the saturated liquid state as changed in the expander in the low temperature gas state to absorb external heat.

The cooling air supply unit includes a blow fan 115 mounted at a surface of a rear wall of the freezing chamber 103 and forcibly ventilating air cooled while passing the evaporator 106; a panel 114 disposed at a front side of the blow fan 115 and having a plurality of cooling air discharge holes 112 for supplying cooling air into the freezing chamber 103; a cooling air supply passage 117 formed penetrating the wall 105 to introduce the cooling air

ventilated from the blow fan 115 to the refrigerating chamber 109; a cooling air discharge duct 118 mounted at a rear side of the refrigerating chamber 109 and communicating with the cooling air supply passage 117 to guide the cooling air supplied to the cooling air supply passage 117 into the refrigerating chamber 109; and a cooling air inlet passage 116 formed penetrating the wall 105 to allow the cooling operation-completed air after having been circulated in the refrigerating chamber 109 to be re-introduced into the evaporator 106 and cooled.

The refrigerant discharge duct 118 includes a plurality of cooling air discharge holes 119 through which cooling air is discharged into the refrigerating chamber 109.

As shown in Figure 2, the vegetable room is configured by the lowermost shelf of the plurality of shelves 107 and a vegetable box 108 disposed at the lower side of the lowermost shelf and opened upwardly with a receptacle space with a certain volume therein.

As the vegetable box 108 is slid forwardly and backwardly at the lower side of the shelf 107, a storage stuff is received/taken away, and a space (h) is maintained between the shelf 107 and the vegetable box 108.

The operation of the conventional refrigerator will now be described.

First, when the refrigerating cycle is driven and the blow fan 115 is rotated, air is cooled while passing the refrigerating cycle and discharged to the cooling air discharge hole 112 of the panel 114 and to the cooling air supply passage 117 by the blast pressure of the blow fan 115.

The cooling air being discharged into the cooling air discharge hole 112 circulates in the freezing chamber 103 to perform a cooling operation on the freezing food items stored in the freezing chamber 103.

5 The cooling air supplied to the cooling air supply passage 117 is introduced into the cooling air discharge duct 118 and then discharged into the refrigerating chamber 109 through the cooling air discharge hole 119 formed at the cooling air discharge duct 118.

10 The cooling air, which has been discharged into the refrigerating chamber 109, performs a cooling operation on the refrigerating food items received in the shelves 107 of the refrigerating chamber 109 and in the vegetable box 108 while circulating in the refrigerating chamber 109.

15 At this time, as the cooling air directly contacts with the refrigerating food items received on the shelves 107 and in the vegetable box 108, the cooling air takes the moisture from the refrigerating food items, containing more moisture, and as the cooling air is re-introduced into the refrigerating cycle through the cooling air inlet passage 116 formed at the wall 105, it is cooled again. The moisture moved along with the cooling air is congealed at the surface of the evaporator 106, is defrost in a frost-removing operation for the evaporator 106 and discharged outwardly.

20 Therefore, in a state that the refrigerating chamber door 113 is closed, the humidity inside the refrigerating chamber 109 is gradually lowered down due to the circulation of cooling air.

However, the conventional refrigerator has the following problems.

That is, first, since the vegetable box 108 is opened upwardly, cooling air supplied into the refrigerating chamber 109 is introduced into the space between the vegetable box 108 and the shelf 107 to directly contact with the food items in the vegetable box 108. Accordingly, for food items requiring a suitable moisture in the vegetable box 108, because their moisture would be taken away by the cooling air, freshness of the food items is degraded and storage duration is shortened.

In addition, since the vegetable box is opened upwardly, if the refrigerating chamber door is opened and closed, external air of the refrigerator can be possibly introduced into the vegetable box.

Therefore, if an environment outside the refrigerator is relatively humid, the outside moisture would be introduced into the vegetable box whenever the refrigerating chamber door is opened and closed, damping the dried food items in the vegetable box which need to be maintained dried.

Meanwhile, if the environment outside the refrigerator is relatively dry, the outside dried air would be introduced into the vegetable box whenever the refrigerating door is opened and closed, drying the food items such as fruits or vegetables in the vegetable box which need to be maintained with moisture. Then, the storage duration of the food items is shortened and freshness of the food items is degraded.

DISCLOSURE OF THE INVENTION

Therefore, it is an object of the present invention to provide a vegetable

room for a refrigerator that is capable of maintaining food items stored in a vegetable box fresh regardless of environmental conditions outside a refrigerator by providing a box cover to close a vegetable box to prevent external air introduced in opening and closing a refrigerator door and cooling air inside a refrigerator from being introduced into the vegetable box and forming a cooling air ventilating hole at the box cover which can be opened and closed to introduce cooling air into the vegetable box or cut off introduction of cooling air into the vegetable box according to environment outside the refrigerator.

Another object of the present invention is to provide a vegetable room for a refrigerator in which a cooling air discharge hole of a cooling air discharge duct provided at a rear side is positioned to face a vegetable box and a nozzle is provided at a front side of the cooling air discharge hole to increase a cooling air discharge speed, so that cooling air can be smoothly circulated around the vegetable box to quickly perform a cooling operation on food items stored in the vegetable box and cooling air can be smoothly introduced into the vegetable box to preserve food items stored in the vegetable box fresh for a long period when a cooling air ventilating hole remains open.

To achieve these and other advantages and in accordance with the purpose of the present invention, as embodied and broadly described herein, there is provided a vegetable room for a refrigerator including: a vegetable box disposed inside a refrigerator in which a cooling air supply unit is provided to circulate cooling air therein and a plurality of shelves are provided, and having a receptacle space for receiving food items therein opened upwardly; a box cover

for covering an opening side of the vegetable box to close the receptacle space of the vegetable box and having a plurality of cooling air ventilating holes formed at one side thereof to introduce cooling air into the vegetable box; a cover support unit interposed between the box cover and the shelf to support the box cover at the shelf; a plurality of opening and closing members for opening and closing the cooling air ventilating holes of the box cover; and an operating unit for operating the opening and closing members simultaneously.

To achieve the above objects there is also provided a vegetable room for a refrigerator in which a cooling air discharge hole of a cooling air discharge duct mounted at a rear side of a refrigerator is provided between a box cover and a shelf so that cooling air can be directly introduced between the box cover and the shelf, and a nozzle is provided at a front side of the cooling air discharge hole and formed with a sectional area diminished as it goes from the rear side to the front side in order to increase the discharge speed of cooling air.

20

MODES FOR CARRYING OUT THE PREFERRED EMBODIMENTS

Figure 3 is a vertical-sectional view showing a vegetable room for a refrigerator in accordance with the present invention, and Figure 4 is an exploded assembled view of a vegetable room for a refrigerator in accordance with the present invention.

As shown in Figures 3 and 4, a vegetable room for a refrigerator in accordance with the present invention includes: a vegetable box 20 disposed inside a refrigerating chamber and provided at a lower side of a shelf 10 for receiving food items thereon, and having a receptacle space (S) with a predetermined capacity upwardly opened to receive fruits, vegetables or functional storage stuffs therein; a box cover 30 for covering an opening side of the vegetable box 20 to close the receptacle space of the vegetable box 20 and having a plurality of cooling air ventilating holes 31 and 41 formed at one side thereof in order to allow cooling air to be introduced into the vegetable box 20; a cover support unit 22 interposed between the box cover 30 and the shelf 10 and supporting the box cover 30 at the lower side of the shelf 10; a plurality of opening and closing members 33 and 43 for opening and closing the cooling air ventilating holes of the box cover 30; and an operating unit 24 installed between the shelf 10 and the box cover 30 and operating the opening and closing members 33 and 43 simultaneously.

A cooling air discharge hole 119 of a cooling air discharge duct 118 is provided between the box cover 30 and the shelf 10 at a rear side of the refrigerator in order to discharge cooling air into the refrigerator, and a nozzle

120 is formed at a front side of the cooling air discharge hole 119 with a sectional area diminished as it goes from the rear side to the front side in order to increase a discharge speed of cooling air.

Accordingly, cooling air is smoothly circulated around the vegetable box
5 20 and quickly performs a cooling operation on food items preserved in the vegetable box 20, and when the cooling air ventilating holes 31 and 41 are opened, cooling air can be smoothly introduced into the vegetable box 20.

The nozzle 120 is preferably positioned at a rear side of the rearmost cooling air ventilating hole, so that when the cooling air ventilating holes 31 and
10 41 are opened, cooling air can be smoothly introduced into the vegetable box 20.

As shown in Figures 5 and 6, the box cover 30 is formed in a square panel shape like the shelf 10 by using a transparent and light material.

Preferably, a plurality of ribs 35 are formed at a lower side of the box
15 cover 30 to collect moisture existing in the vegetable box 20. The rib 35 has a grid form with a certain width and height so as to heighten a water-collection effect. As moisture existing inside the vegetable box 20 is collected at the grids of the rib 35, it is prevented from being discharged outwardly from the vegetable box 20.

20 The cooling air ventilating holes 31 and 41 of the box cover 30 are formed long and approximately perpendicular to the direction that cooling air is introduced, in order to allow cooling air to be smoothly introduced into the vegetable box 20.

There can be formed a plurality of cooling air ventilating holes within the area of the box cover 30. In the present invention, cooling air ventilating holes 31 and 41 are formed at a front side and at a rear side of the box cover 30. That is, a first cooling air ventilating hole 31 is formed at the front side of the box cover 30 and a second cooling air ventilating hole 41 is formed at the rear side of the box cover 30.

The cover support unit 22 consists of a hinge bracket 12 formed downwardly at both sides of the shelf 10 and having a hinge hole 14 formed long in a vertical direction, and a hinge shaft 32 formed extended at both sides of the box cover 30 and inserted to be movable in a vertical direction into the hinge hole 14 of the hinge bracket 12.

The cover support unit 22 is preferably formed eccentric toward the front side on the basis of the center of the box cover 30 so that when the vegetable box 20 is separated from the lower side of the shelf 10, the box cover 30 is somewhat lifted at its front side compared to the rear side owing to the self-weight.

The hinge bracket 12 and the hinge shaft 32 are positioned such that a distance (L1) from the front side of the shelf 10 and from the box cover 30 is shorter than a distance (L2) from the rear side of the shelf 10 and from the box cover 30.

Meanwhile, though not shown in the drawing, the hinge bracket 12 may be formed at the box cover 30, and accordingly, the hinge shaft 32 may be formed at the shelf 10.

The opening and closing members 33 and 43 are formed as a first opening and closing member 33 installed at the first cooling air ventilating hole 31 and a second opening and closing member 43 installed at the second cooling air ventilating hole 41, and formed plate with a predetermined thickness corresponding to the shape of the first and second cooling air ventilating holes 31 and 41.

Cylindrical support shafts 38 and 48 are formed extended at both sides of the first and second opening and closing members 33 and 43. The support shafts 38 and 48 are inserted rotatably into insertion holes 37 and 47 formed at both sides of the first and second cooling air ventilating holes 31 and 41 in order to rotatably support the first and second opening and closing members 33 and 43 at the inner side of the first and second cooling air ventilating holes 31 and 41.

As shown in Figure 7, preferably, the support shafts 38 and 48 are formed eccentric toward the front side or toward the rear side on the basis of the center so that the first and second opening and closing members 33 and 43 are rotated by self-weight to close the first and second cooling air ventilating holes 31 and 41 after the first and second cooling air ventilating holes 31 and 41 are opened.

Either an outer circumferential surface of the support shafts 38 and 48 or an inner circumferential surface of the insertion holes 37 and 47 are formed to be polyhedral so that when a user opens and closes the first and second cooling air ventilating holes 31 and 41 by directly rotating the first and second

opening and closing members 33 and 43 without using the operating unit 24, each of the opening and closing members 33 and 43 can maintain a rotation angle.

As shown in Figures 8 and 9, the operating unit 24 consists of a driving unit 26 interposed between the box cover 30 and the shelf 10 and rotating the first opening and closing member 33 to open the first cooling air ventilating hole 31; and an coupling unit 28 for interacting with the driving unit 26 to simultaneously rotate the first and second opening and closing members 33 and 43 to open the second cooling air ventilating hole 41.

As shown in Figures 10 and 11, the driving unit 26 consists of a first protrusion 34 formed protruded upwardly from the first opening and closing member 33; a knob 13 installed to be movable linearly at one side of the shelf 10; and a second protrusion 15 formed protruded downwardly from the knob 13 and rotating the first opening and closing member 33 by interaction with the first protrusion 34 when the knob 13 is moved.

A guide groove 11 is formed at the shelf 10 where the knob 13 is installed, to guide a linear movement of the knob 13, and a guide slot 17 is formed at the inner side of the guide groove 11 to allow the second protrusion 15 to pass through the shelf 10 and guides a linear movement of the second protrusion 15.

The first protrusion 34 converts the linear movement of the knob 13 into a rotational movement of the opening and closing member 33 by interacting with the second protrusion 15. The first protrusion 34 is formed inclined at a

certain angle toward the second protrusion 15 so that it can rotate the opening and closing member 33 by being pushed by the second protrusion 15.

Preferably, the first protrusion 34 and the second protrusion 15 have a curved shape with a certain curvature at portions where they are mutually contacted with each other so that they can be smoothly slid.

As described above in the preferred embodiment of the present invention, the driving unit 26 is preferably installed at the front side near the refrigerator door, that is, at the side of the first opening and closing member 33, in consideration of users' convenience in operation, but, without being limited thereto, may be installed at the rear side of the refrigerator, that is, at the side of the second opening and closing member 43.

The coupling unit 28 consists of a connection pin 44 extended downwardly from the first and second opening and closing members 33 and 43, and a connection rod 45 hinge-connected at the lower side of the connection pin 44 and transmitting a rotational force of the first opening and closing member 33 to the second opening and closing member 43 when the first opening and closing member 33 is rotated by the driving unit 26.

The operation and effect of the vegetable room of the refrigerator in accordance with the present invention will now be described.

Food items containing moisture such as fruits or vegetables or storage stuffs desired to be maintained in a dry state are stored in the receptacle space of the vegetable box 20. In order to maintain the freshness of such food items and storage stuffs at the maximum, each characteristic of storage stuffs should

be preserved harmoniously through the following manipulation.

To begin with, the process of mounting the box cover 30 at the upper portion of the vegetable box 20 to close the receptacle space of the vegetable box 20 in order to prevent the food items inside the vegetable box 20 to directly
5 contact with cooling air inside the refrigerator and with outdoor air of the refrigerator will now be described with reference to Figures 12A to 12C.

First, food items are put in the receptacle space of the vegetable box 20 and the vegetable box 20 is inserted into the lower side of the shelf 10.

As shown in Figure 12A, before the vegetable box 20 is inserted into the
10 lower side of the shelf 10, the box cover 30 is inclined with its front side lifted. At this time, the vegetable box 20 is advanced until an upper end corner of the rear side of the vegetable box 20 is in contact with the rear side of the box cover 30. Then, as shown in Figure 12B, the hinge shaft 32 provided at both sides of the box cover 30 is moved upwardly along the hinge hole 14 formed at the hinge
15 bracket 12 provided at both sides of the shelf 10 and rotated such that the front side of the box cover 30 descends and the rear side thereof is lifted.

And then, as shown in Figure 12C, after the vegetable box 20 is placed at a right position of the lower side of the shelf 10, the box cover 30 descends to be mounted at an upper side of the vegetable box 20.

20 Accordingly, the receptacle space of the vegetable box 20 is closed as the box cover 30 is mounted at the upper surface of the vegetable box 20, and thus, the food items stored in the receptacle space is prevented from directly contacting with cooling air circulating inside the refrigerator and at the same

time outdoor air outside the refrigerator is prevented from being introduced thereinto and affecting the food items when the refrigerator door is opened and closed.

Meanwhile, if a condition outside the refrigerator is humid and the refrigerator door is opened and closed, when a food item is put into the vegetable box 20, the humid air is bound to be introduced into the vegetable box 20 together with the food item.

At this time, if a storage stuff preserved in the vegetable box 20 is in need of drying, since the vegetable box 20 is in a closed state by means of the box cover 30, the moisture introduced into the vegetable box 20 will not be discharged outwardly from the vegetable box 20 and cooled therein, making the storage stuff which needs drying to be damp.

In such a case, cooling air is let to be introduced into and circulated in the vegetable box 20 so as to take moisture away from the vegetable box 20 and discharge it outwardly, thereby maintaining the storage stuff in a dried state.

When cooling air is desired to be introduced into the vegetable box 20, the first and second cooling air ventilating holes 31 and 41 are opened, rather than detaching the box cover 30, processes of which will now be described.

First, when the knob 13 installed at the shelf 10 is slid in an opening direction (that is, in the right direction in Figure 10 or 11), the second protrusion 15 of the knob 13 pushes the curved face of the first protrusion 34 of the opening and closing member 33. Then, being pushed, the first protrusion 34

moved downwardly, and the first opening and closing member 33 is rotated centering around the support shaft 38 extendedly formed at both sides thereof, thereby opening the first cooling air ventilating hole 31.

At the same time, the second opening and closing member 43 receives
5 the rotational force of the first opening and closing member 43 through the connection 44 and the connection rod 45 the second opening and closing member 43 and is rotated to open the second cooling air ventilating hole 41.

As the first and second cooling air ventilating hole 31 and 41 are opened,
cooling air circulated in the refrigerator is introduced into the vegetable box 20
10 and discharges moisture from the vegetable box 20, so that the vegetable box 20 can be maintained dry.

At this time, the cooling air discharge hole 119 is positioned between the box cover 30 and the shelf 10, cooling air can be smoothly introduced into the vegetable box 20, and the nozzle provided at the cooling air discharge hole 119
15 makes discharge speed of cooling air fast, so that cooling air is fast introduced into and circulated in the vegetable box 20. Thus, dryness of storage stuffs inside the vegetable box 20 can be more effectively heightened.

Meanwhile, if a food item of which moisture needs to be maintained is preserved in the vegetable box, the first and second cooling air ventilating holes
20 31 and 32 must be closed to prevent the food item from being dehumidified by cooling air.

The first and second cooling air ventilating holes 31 and 32 are closed as follows.

That is, when the knob 13 installed at the shelf 10 is slid in a closing direction (that is, in the left direction in Figure 10 or 11), the first opening and closing member 33 is rotated centering around the support shaft 38 due to its self weight, closing the first cooling air ventilating hole 31 of the box cover 30.

5 At the same time, like the first opening and closing member, the second opening and closing member 43 is rotated centering around the support shaft 48 by its self-weight, closing the second cooling air ventilating hole 41.

At this time, since the cooling air discharge hole 119 is positioned between the box cover 30 and the shelf 10 and the nozzle 120 accelerating the
10 speed of cooling air is provided at the front side of the cooling air discharge hole 119, cooling air is smoothly circulated around the vegetable box 20 to perform a rapid cooling operation on food items kept in the vegetable box 20.

Accordingly, the receptacle space of the vegetable box 20 is closed and introduction of cooling air to moisture-containing food items which need to
15 maintain the moisture as it is, such as vegetables and fruits, is cut off. In this manner dehydration is prevented.

At this time, moisture may be taken away from the food items in the receptacle space, but since this moisture ascends and is coagulated at the rib 35 formed protruded at a lower side of the box cover 30, moisture leakage is
20 prevented and thus the humidity of the food items can be effectively maintained.

As so far described, the vegetable room for a refrigerator in accordance with the present invention has many advantages.

That is, the box cover is provided to cover the opening side of the

vegetable box and the cooling air ventilating hole is formed at the box cover and closed when vegetables or fruits are preserved. Accordingly, preserved in the hermetic state, those moisture-maintaining desired food items will not be in contact with cooling air, so that dehydration of them can be prevented.

5 Especially, when food items which needs drying are preserved under the condition of a humid environment outside the refrigerator, the cooling air ventilating hole is opened to let cooling air to be in contact with the dry-kept food items in the vegetable box and continuously move moisture generated from the food items by means of cooling air, thereby maintaining the food items in the dry
10 state. In this manner, the storage condition of food items preserved in the vegetable box can be optimized.

 The plurality of cooling air ventilating holes are formed at the box cover and high speed cooling air is directly supplied between the box cover and the shelf through the cooling air discharge hole of the cooling air discharge duct and
15 the nozzle. Thus, cooling air can be smoothly introduced into the vegetable box.

 In addition, the cooling air ventilating hole can be simply opened and closed without detaching the box cover in introducing cooling air into the vegetable box or cut off cooling air with the vegetable box.

 As the present invention may be embodied in several forms without
20 departing from the spirit or essential characteristics thereof, it should also be understood that the above-described embodiments are not limited by any of the details of the foregoing description, unless otherwise specified, but rather should be construed broadly within its spirit and scope as defined in the

appended claims, and therefore all changes and modifications that fall within the metes and bounds of the claims, or equivalence of such metes and bounds are therefore intended to be embraced by the appended claims.

CLAIMS

1. A vegetable room for a refrigerator comprising:

a vegetable box disposed inside a refrigerator in which a cooling air
5 supply unit is provided to circulate cooling air therein and a plurality of shelves
are provided, and having a receptacle space for receiving food items therein
opened upwardly;

a box cover for covering an opening side of the vegetable box to close
the receptacle space of the vegetable box and having a plurality of cooling air
10 ventilating holes formed at one side thereof to introduce cooling air into the
vegetable box;

a cover support unit interposed between the box cover and the shelf to
support the box cover at the shelf;

a plurality of opening and closing members for opening and closing the
15 cooling air ventilating holes of the box cover; and

an operating unit for operating the opening and closing members
simultaneously.

2. The vegetable room of claim 1, wherein the cover support unit is
20 formed eccentric toward the front side on the basis of the center of the box
cover so that when the vegetable box is separated from the lower side of the
shelf, the front side of the box cover is relatively lifted compared to the rear side
thereof due to its self weight.

3. The vegetable room of claim 2, wherein the cover support unit comprises:

a hinge bracket extended downwardly from both left and right sides of the shelf and having a hinge hole formed therein; and

5 a hinge shaft extended at both left and right sides of the box cover and inserted into the hinge hole so as to be movable vertically.

4. The vegetable room of claim 3, wherein the hinge hole is formed long vertically.

10

5. The vegetable room of claim 2, wherein the cover support unit comprises:

a hinge bracket extended upwardly from both left and right sides of the vegetable box and having a vertically long hinge hole formed therein; and

15 a hinge shaft extended to both left and right sides of the shelf and inserted into the hinge hole so as to be movable vertically.

6. The vegetable room of claim 1, wherein the cooling air ventilating hole is formed long perpendicular to the direction in which cooling air is introduced, in order to allow cooling air to be smoothly introduced into the receptacle space of the vegetable box.

20

7. The vegetable room of claim 1, wherein the opening and closing

member comprises:

a first opening and closing member rotatably supported at an inner side of the first cooling air ventilating hole formed at one side of the vegetable box; and

5 at least one or more second opening and closing members rotatably supported at an inner side of at least one or more second cooling air ventilating holes formed separated with a certain space from the first cooling air ventilating hole.

10 8. The vegetable room of claim 7, wherein the first and second opening and closing members are formed platy with a certain thickness and include a cylindrical support shaft extended at both sides thereof, the support shaft being rotatably inserted into an insertion hole formed at both sides of the first and second cooling air ventilating holes in order to rotatably support the first
15 and second opening and closing member at the inner side of the cooling air ventilating holes.

9. The vegetable room of claim 8, wherein either an outer circumferential surface of the support shaft or an inner circumferential surface of
20 the insertion hole are formed to be polyhedral so that rotation angle of the first and second opening and closing members can be controlled by steps.

10. The vegetable room of claim 8, wherein the support shaft is

formed eccentric toward a front side or toward a rear side on the basis of the center of the first and second opening and closing members so that the first and second opening and closing members can close the cooling air ventilating hole by its rotation according to self weight.

5

11. The vegetable room of claim 7, wherein the operating unit comprises:

a driving unit interposed between the box cover and the shelf and opening the first cooling air ventilating hole by rotating the first opening and closing member; and

10

an coupling unit for simultaneously rotating the first and second opening and closing members to open the second cooling air ventilating hole by interacting with the driving unit.

15

12. The vegetable room of claim 11, wherein the driving unit is installed at the front side.

13. The vegetable room of claim 11, wherein the driving unit is installed at a rear side of the refrigerator.

20

14. The vegetable room of claim 11, wherein the driving unit comprises:

a first protrusion formed protruded upwardly from the first opening and

closing member;

a knob installed to be movable linearly at one side of the shelf; and

a second protrusion protruded downwardly from the knob and rotating the first opening and closing member by interaction with the first protrusion
5 when the knob is moved.

15. The vegetable room of claim 14, wherein a guide groove is formed at the shelf to guide a linear movement of the knob.

10 16. The vegetable of claim 15, wherein a guide slot is formed at the inner side of the guide groove to allow the second protrusion to pass through the shelf and guide a linear movement of the second protrusion.

15 17. The vegetable room of claim 14, wherein the first protrusion is formed inclined at a certain angle in order to rotate the opening and closing member by being pushed by the second protrusion.

20 18. The vegetable room of claim 17, wherein the first protrusion and the second protrusion respectively have a curved shape with a certain curvature at portions where they are mutually contacted with each other so that they can be smoothly slid.

19. The vegetable room of claim 11, wherein the coupling unit

comprises:

a connection pin extended downwardly from the first and second opening and closing members; and

5 a connection rod hinge-connected at the lower side of the connection pin and transmitting a rotational force of the first opening and closing member to the second opening and closing member when the first opening and closing member is rotated by the driving unit.

10 20. The vegetable room of claim 1, wherein a plurality of ribs are formed at the bottom of the box cover with a certain height and with a certain width to collect moisture inside the vegetable box.

15 21. The vegetable room of claim 20, wherein the ribs have a grid form.

22. The vegetable room of claim 1, wherein a cooling air discharge hole of a cooling air discharge duct for discharging cooling air into a refrigerating chamber is positioned between the box cover and the shelf at the rear side of the refrigerator so that cooling air can be directly supplied between
20 the box cover and the shelf.

23. The vegetable room of claim 22, wherein a nozzle is provided at a front side of the cooling air discharge hole, of which sectional area is

diminished as it goes from a rear side to a front side in order to increase the discharge speed of cooling air.

24. The vegetable room of claim 23, wherein the nozzle is provided
- 5 to be positioned at a rear side of the rearmost cooling air ventilating hole.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/KR 02/02494

CLASSIFICATION OF SUBJECT MATTER

IPC⁷: F25D 17/08 , F25D 25/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC⁷: F25D

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

WPI , EPODOC , PAJ

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

* Special categories of cited documents:

„A“ document defining the general state of the art which is not considered to be of particular relevance

„E“ earlier application or patent but published on or after the international filing date

„L“ document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

„O“ document referring to an oral disclosure, use, exhibition or other means

„P“ document published prior to the international filing date but later than the priority date claimed

„T“ later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

„X“ document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

„Y“ document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

„&“ document member of the same patent family
